

已知 1900.1.1 是星期一，对于一个给定的年份和月份，输出这个月的最后一天是星期几

a) 1900.1.1 是星期一

b) 非闰年的 2 月是 28 天，闰年是 29 天

c) 闰年定义：公元年数能被 4 整除且又不能 100 整除是闰年；能被 400 整除也是闰年

输入格式：

两个整数，分别代表年份和月份

输出格式：

星期数：0 代表星期日，1 代表星期 1，...，6 代表星期 6

1、编写函数实现功能

2、编写测试用例

1、

```
#!/usr/bin/env python
# encoding: utf-8
"""
@author: Hank zhang
@contract:
@file: homework4_ex.py
@time: 2016/10/23 11:34
"""

# 非闰年 每月天数
monthdays = {1:31, 2:28, 3:31, 4:30, 5:31, 6:30, 7:31, 8:31, 9:30, 10:31, 11:30, 12:31}
# 非闰年与闰年对应的天数
yeardays = {0:365, 1:366}

# 计算是否是闰年
def leapYear(year):
    assert year>0, u"输入年份必须大于零的整数"
    if (year%4==0 and year%100!=0) or (year%400==0):
        return 1
    return 0

# 计算星期几
def sumWeekday(days):
    # assert type(days) == type(int), u"输入天数必须大于零的整数"

    # 星期
    week = {-6:u'星期一', -5:u'星期二', -4:u'星期三', -3:u'星期四', -2:u'星期五', -1:u'星期六', 0:u'星期日', \
            1:u'星期一', 2:u'星期二', 3:u'星期三', 4:u'星期四', 5:u'星期五', 6:u'星期六'}
    }
```

```

        return week[days%7]

#计算与1990年1月1日相距的时间
def sumDays(year, month):
    assert year>0 and month>0, u"输入年月份必须大于零的整数"
    days = 0
    if year >= 1990:
        for elem in range(1990, year):
            days += yeardays[leapYear(elem)]
        for elem in range(1, month+1):
            if leapYear(year)==1 and elem ==2:
                days += monthdays[elem] + 1
            else:
                days += monthdays[elem]
    else:
        for elem in range(year, 1990):
            days -= yeardays[leapYear(elem)]
        for elem in range(1, month+1):
            if leapYear(year)==1 and elem ==2:
                days += monthdays[elem] + 1
            else:
                days += monthdays[elem]
    return days

if __name__ == "__main__":
    year = input("请输入年份: ")
    month = input("请输入月份: ")
    days = sumDays(year, month)
    print sumWeekday(days)

```

2、

```

import unittest

from src.homework4_ex import sumWeekday

class MyTestCase(unittest.TestCase):
    def test_something(self):
        test_dict = {(2016, 10): u'星期一', (2016, 9): u'星期五', (2016, 8): u'星期三', (2016, 7): u'星期日',
